05.09.2016

- GLMM are used in a wide range of different applications for
  - Inference
  - Prediction
- More sources of data → more hypothetical explanatory variables →
  - Model selection
  - Model averaging
- Posterior marginal model probabilities are used to
  - Estimate quality of the models
  - Serve as weights in Bayesian model averaging
- Efficient search algorithms for evaluating posterior marginal model probabilities are required since
  - The number of models to select from is exponential in the number of candidate variables
  - The search space has numerous sparsely located local extrema
  - Time and computing resources are limited

# Bayesian vs. Frequentist statistics

Frequentist: obtain  $\hat{\theta}$  with CI by MLE, MM, MD etc.

vs.

$$\text{Bayesian: obtain } p(\theta|\mathbb{D}) = \frac{p(\mathbb{D}|\theta)p(\theta)}{p(\mathbb{D})} = \frac{p(\mathbb{D}|\theta)p(\theta)}{\int_{\Omega_{\theta'}} p(\mathbb{D}|\theta')p(\theta')d\theta'}$$

## Frequentist vs. Bayesian

*Two Trends in  
Data Analysis:*

Copyright © 2015 John K. Kruschke

Jerzy Neyman

Harold Jeffreys

Frequentist	Bayesian
Probability is a long-run average	Probability is a degree of belief
There is a true Model, the Data is a random realization	The Data is true/fixed, Models have probabilities
Probability of the data given a hypothesis (Likelihood)	Probability of a hypothesis given the data
Each repeated experiment/observation starts from ignorance	Can incorporate prior knowledge: probabilities can be updated

**Figure:** Paradigms shifts (left, adopted from John K. Kruschke, [doingbayesiandataanalysis.blogspot.no](http://doingbayesiandataanalysis.blogspot.no)) and differences between the paradigms (right, adopted from Andres Lopez-Sepulcre, [www.slideshare.net/andreslopezsepulcre](http://www.slideshare.net/andreslopezsepulcre))

## Logistic Bayesian regression

$$y_t = y | p_t \sim \text{Binom}(1, p_t) \quad (1)$$

$$p_t = \frac{e^{\beta_0 + \sum_{i=1}^p \beta_i X_{t,i}}}{1 + e^{\beta_0 + \sum_{i=1}^p \beta_i X_{t,i}}} \quad (2)$$

$$\beta | \gamma \sim N_u(\mu_\beta, \Sigma_\beta = g(X_\gamma' X_\gamma)^{-1}), u = \sum_{i=1}^p \gamma_i \quad (3)$$

**Notice that priors appear here**

# Bayesian classification using averaging across models

Figure: Bayesian Artificial Neuron Network for Classification

$$\hat{Y} = \mathbb{I}\{\hat{E}[Y|D] \geq 0.5\}, \hat{E}[Y|D] = \sum_{\gamma \in \mathbb{V}^*} \hat{E}[y_\gamma | \gamma, D] \hat{p}(\gamma|D)$$

# Bayesian Generalized Linear Mixed Model

$$Y_t | \mu_t \sim f(y | \mu_t), t \in \{1, \dots, T\} \quad (4)$$

$$\mu_t = g^{-1}(\eta_t) \quad (5)$$

$$\eta_t = \gamma_0 \beta_0 + \sum_{i=1}^p \gamma_i \beta_i X_{ti} + \delta_t \quad (6)$$

$$\boldsymbol{\delta} = (\delta_1, \dots, \delta_T) \sim N_T(\mathbf{0}, \boldsymbol{\Sigma}_b). \quad (7)$$

- $\beta_i \in \mathbb{R}, i \in \{0, \dots, p\}$  are regression coefficients
- $\boldsymbol{\Sigma}_b = \boldsymbol{\Sigma}_b(\boldsymbol{\psi}) \in \mathbb{R}^T \times \mathbb{R}^T$  is the covariance of the random effect  $\delta_t$
- $g(\cdot)$  is a proper link function
- $\gamma_i \in \{0, 1\}, i \in \{0, \dots, p\}$  are latent indicators defining if covariate  $X_{ti}$  is included into the model ( $\gamma_i = 1$ ) or not ( $\gamma_i = 0$ )

**We use a fully Bayesian approach, hence specify priors**

$$\gamma_i \sim \text{Binom}(1, q) \quad (8)$$

$$q \sim \text{Beta}(\alpha_q, \beta_q) \quad (9)$$

$$\beta|\gamma \sim N_u(\mu_\beta, \Sigma_\beta), u = \sum_{i=1}^p \gamma_i \quad (10)$$

$$\psi \sim \varphi(\psi). \quad (11)$$

- $q$  is the prior probability of including a covariate into the model
- $\alpha_q, \beta_q$  are hyper parameters for the prior on  $q$
- $\mu_\beta, \Sigma_\beta$  are hyper parameters for the prior on  $\beta|\gamma$
- $\psi$  are the hyper parameters of the random effect

## Let:

- $\gamma = \vec{\gamma}$  define a model itself, i.e. which covariates are addressed
- $\theta$  define parameters of the model

## Then:

- $\exists 2^{p+1}$  different models

## Goals:

- $p(\gamma, \theta | \mathbb{D})$  posterior distribution of parameters and models
- $p(\gamma | \mathbb{D})$  marginal posterior probabilities of the models
- $p(\mathcal{G} | \mathbb{D})$  marginal posterior probabilities of the quantiles of interest  $\mathcal{G}$

- **Notice that**  $p(\gamma, \theta | \mathbb{D}) = p(\theta | \gamma, \mathbb{D}) p(\gamma | \mathbb{D})$
- $p(\theta | \gamma, \mathbb{D})$  and  $\log p(\mathbb{D} | \gamma)$  can be efficiently obtained by INLA
- **Notice that**  $p(\gamma | \mathbb{D}) = \frac{e^{\log p(\mathbb{D} | \gamma) + \log p(\gamma)}}{\sum_{\gamma' \in \Omega_\gamma} e^{\log p(\mathbb{D} | \gamma') + \log p(\gamma')}}$
- $\widehat{p}(\gamma | \mathbb{D}) = \frac{e^{\log p(\mathbb{D} | \gamma) + \log p(\gamma)}}{\sum_{\gamma' \in \mathbb{V}} e^{\log p(\mathbb{D} | \gamma') + \log p(\gamma')}}$
- $\mathbb{V}$  is the **subspace** of  $\Omega_\gamma$  to be **efficiently explored**
- **Notice that** for  $p(\gamma) = p(\gamma') \forall \gamma, \gamma' \in \Omega_\gamma$ :
- $p(\gamma | \mathbb{D}) \gg p(\gamma' | \mathbb{D})$  if  $\log p(\mathbb{D} | \gamma) > \log p(\mathbb{D} | \gamma')$  often  $\implies$
- **Near modal values in terms of log MLIK are particularly important** for construction of reasonable  $\mathbb{V} \subset \Omega_\gamma$ , **missing them can dramatically influence** posterior in the original space  $\Omega_\gamma$

# Possible ways to explore $\mathbb{V} \subset \Omega_\gamma$

**Main challenges are multimodality in  $\Omega_\gamma$  and its size.**

- Full enumeration of  $\Omega_\gamma$  - infeasible for large dimensions
- Random walk in  $\Omega_\gamma$  including simple MCMC - does not take advantage of the structure of  $\Omega_\gamma \implies$  too slow
- Greedy optimization with numerous initial points - end up in local optima
- MCMC with mode jumping proposals seems to be a good idea

# MCMC with locally optimized proposals

**Tjelmeland and Hegstad [6]** suggested continuous mode jumping proposals, **Storvik [5]** considers a more general setup, **we suggest mode jumping proposals** in the **discrete parameter spaces**.

Figure: Locally optimized with randomization proposals

# Local combinatorial optimizers

- **Greedily optimized local improvements** (implemented)
- *Simulated annealing based local improvements* (implemented)
- *MCMC based local improvements* (implemented)
- Other local metaheuristics (TA, ant colony optimization, local genetic algorithms, etc) (not addressed yet)
- *Combinations of them* (implemented)

# Allowed transitions

Proposal $q(\gamma^* \gamma)$	Label
$\frac{\prod_{i \in \{j(1), \dots, j(S)\}} \rho_i}{\binom{p}{S}(\eta - \zeta + 1)}$	Random change with random size of the neighborhood
$\frac{\prod_{i \in \{j(1), \dots, j(S)\}} \rho_i}{\binom{p}{S}}$	Random change with fixed size of the neighborhood
$\frac{1}{\binom{p}{S}(\eta - \zeta + 1)}$	Swap with random size of the neighborhood
$\frac{\binom{p}{S}^{-1}}{\binom{p}{S}}$	Swap with fixed size of the neighborhood
$\frac{1 - \mathbb{I}(\sum_i^p \gamma_i = P)}{P - \sum_i^p \gamma_i + \mathbb{I}(\sum_i^p \gamma_i = P)}$	Uniform addition of a covariate
$\frac{1 - \mathbb{I}(\sum_i^p \gamma_i = 0)}{\sum_i^p \gamma_i + \mathbb{I}(\sum_i^p \gamma_i = P)}$	Uniform deletion of a covariate

**Table:** Types of proposals suggested for the moves between the models during MCMC procedure. Here  $S$  is either deterministic or random  $S \sim \text{Unif}\{\zeta, \dots, \eta\}$  size of the neighborhood;  $\rho_i, i \in \{j(1), \dots, j(S)\}$  is the probability of inclusion of variable  $\gamma_i, i \in \{j(1), \dots, j(S)\}$ , which can be either deterministic or adaptive when  $\rho_i, i \in \{j(1), \dots, j(S)\}$  are adaptively updated approximations of the marginal inclusion probabilities;  $\mathbb{I}(\cdot)$  is the identity function;  $p$  is the total number of covariates.

# Application of MCMC with mode jumping proposals

We have shown that the detailed balance equation is satisfied for the following acceptance probabilities:

$$r_m(\gamma_j, \gamma_k) = \min \left\{ 1, \frac{p(\mathbb{D}|\gamma_k)p(\gamma_k)q_s(\gamma_j|\gamma_{j_{K-1}})}{p(\mathbb{D}|\gamma_j)p(\gamma_j)q_s(\gamma_k|\gamma_{k_{K-1}})} \right\}. \quad (12)$$

- $q_s(.|.)$  is the kernel of randomization at the end.

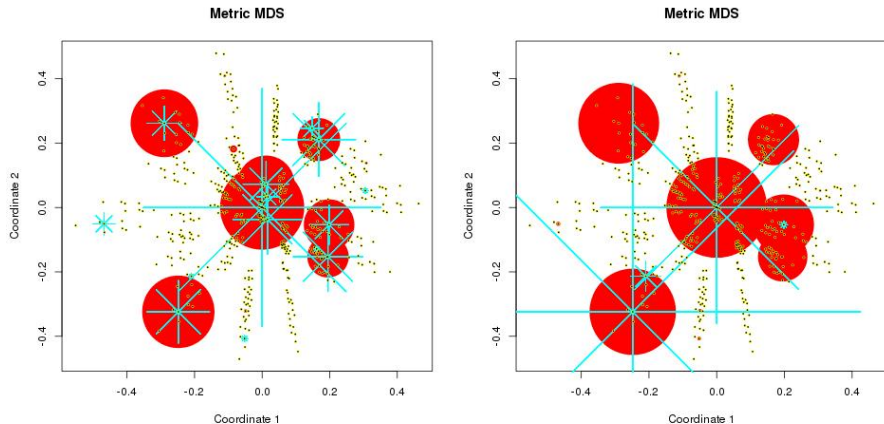

Hence we also obtain alternative MCMC estimators of posterior marginal probabilities

$$\tilde{p}(\gamma|\mathbb{D}) = \frac{\sum_{i=1}^W \mathbb{I}(\gamma_i = \gamma)}{W} \xrightarrow{W \rightarrow \infty} p(\gamma|\mathbb{D}). \quad (13)$$

- $W$  is the number of MCMC iterations (after burn-in)

# How it looks like in reality

Modes are important: the standard MCMC procedure (right) misses two in this example. Visualization is challenging

**Figure:** MDS plots with posterior modes of all found solutions for the approaches

# Application to NEO classification. NASA Space Challenge (<https://github.com/SpaceApps2016/Resources>).

Observations (Bernoulli classifiers):

- Asteroid is a NEO (PHA) object or not (Phocaea)

Variables:

- Rotation period
- Magnitude slope
- Mean anomaly
- Inclination
- Argument of perihelion
- Longitude of the ascending node
- Rms residual
- Semi major axis
- Eccentricity
- Mean motion
- Absolute magnitude
- Other covariates, their interactions, polynomes and etc.

# Application to cosmological simulations or NEO objects classification

**Logistic Bayesian regression** addressed

$$y_t = y | p_t \sim \text{Binom}(1, p_t) \quad (14)$$

$$p_t = \frac{e^{\gamma_0 \beta_0 + \sum_{i=1}^p \gamma_i \beta_i X_{t,i}}}{1 + e^{\gamma_0 \beta_0 + \sum_{i=1}^p \gamma_i \beta_i X_{t,i}}} \quad (15)$$

$$\beta | \gamma \sim N_u(\mu_\beta, \Sigma_\beta = g(X'_\gamma X_\gamma)^{-1}), u = \sum_{i=1}^p \gamma_i \quad (16)$$

$$\gamma_i \sim \text{Binom}(1, q = 0.5). \quad (17)$$

# NEO objects classification. NASA space challenge

## APPARENT MAGNITUDE

## ABSOLUTE MAGNITUDE

# NEO objects classification. NASA space challenge

**20 covariates** addressed in the experiment (both *reasonable* and *heuristic*): Mean anomaly  $\in [0^\circ; 360^\circ)$ ; Argument of perihelion  $\in [0^\circ; 360^\circ)$ ; Longitude of the ascending node  $\in [0^\circ; 360^\circ)$ ; Inclination  $\in [0^\circ; 180^\circ)$ ; Semi major axis  $\in \mathbf{R}^+$ ; Eccentricity  $\in \mathbf{R}^+$ ; Mean motion  $\in \mathbf{R}^+$ ; Absolute magnitude  $\in \mathbf{R}$  (brightness); Rms residual  $\in \mathbf{R}^+$  (brightness error); Eccentricity<sup>2</sup>  $\in \mathbf{R}^+$ ; Absolute magnitude<sup>2</sup>  $\in \mathbf{R}^+$ ; Semi major axis<sup>2</sup>  $\in \mathbf{R}^+$ ; Semi major axis<sup>3</sup>  $\in \mathbf{R}^+$ ; Mean anomaly $\times$ Semi major axis; Mean anomaly $\times$ Semi major axis<sup>2</sup>  $\in \mathbf{R}^+$ ; Mean anomaly $\times$ Semi major axis<sup>3</sup>  $\in \mathbf{R}^+$ ; Argument of perihelion $\times$ Semi major axis  $\in \mathbf{R}^+$ ; Argument of perihelion $\times$ Semi major axis<sup>2</sup>  $\in \mathbf{R}^+$ ; Argument of perihelion $\times$ Semi major axis<sup>3</sup>  $\in \mathbf{R}^+$ ; Longitude of the ascending node $\times$ Semi major axis  $\in \mathbf{R}^+$ .

**Training set** includes 32 NEO and 32 non-NEO objects, **test set** includes 20720 objects (14099 NEO, 6621 non-NEO).

**2<sup>20</sup> models** in total, algorithm was run until ca **2500 models** and ca **10000 models** are visited.

# NEO objects classification. Inference

## Posterior inclusion probabilities and posterior model probabilities

**Figure:** Comparison of marginal inclusion probabilities of the covariates (left) and models on the whole (right)

# NEO objects classification. Bayesian classification

Choice of  $\mathbb{V}^*$  is crucial,  $\mathbb{V}^* = \Omega_\gamma$  - often in-feasible,  $\mathbb{V}^* = \mathbb{V}$  - very precise can be too slow,  $\mathbb{V}^* = \mathbb{V} \cap p(\gamma|\mathbb{D}) \geq \alpha$  - often precise, but is a way faster!!!

Figure: Bayesian Artificial Neuron Network for Classification

$$\hat{Y} = \mathbb{I}\{\hat{E}[Y|\mathbf{D}] \geq 0.5\}, \hat{E}[Y|\mathbf{D}] = \sum_{\gamma \in \mathbb{V}^*} \hat{E}[y_\gamma|\gamma, \mathbf{D}] \hat{p}(\gamma|\mathbf{D})$$

# NEO objects classification. Missing data handling

- Delete models containing NA for the corresponding prediction from  $\mathbb{V}$ .
- Recalculate the posteriors.
- Get model averaged predictions.

Metric MDS

Metric MDS

# NEO objects classification. Results

Quite impressive actually... Surprisingly or not?.. Comments?..

**Remember:**  $\|\text{training set}\| = 64$ ,  $\|\text{test set}\| = 20720$

**Table:** Comparison of performance (Precision, FDR, FNR, Time) of different models

N/B: the best model includes eccentricity<sup>2</sup>, eccentricity, absolute magnitude<sup>2</sup>, absolute magnitude

# Multicore and shared memory issues

1. Share the work done by reference
2. Before assigning a job to a CPU check if the job is already done
3. Thus avoid re-completing jobs & minimize communication times
4. Important to control writing to the shared memory efficiently

Figure: Multiprocessing architecture

# The protein activity data. $2^{88}$ models. Multiple modes

Comparison to other algorithms: BAS, RS (simpler MCMC) on  $2^{20}$  unique models visited for MJMCMC and BAS and  $88 \times 2^{20}$  iterations of RS.

**Figure:** 100000 best mliks found (left) and posterior masses captured (right). Bayesian linear regression with a g-prior is addressed, since no other packages (to our awareness) manage model selection in GLMM

# The protein activity data. $2^{88}$ models. Multiple modes

Checking convergence. Marginal inclusion probabilities

**Figure:** Comparison of marginal inclusion probabilities obtained by the Bayes formula and MCMC approximations from the best run of MJMCMC with  $8.56e + 20$  posterior mass captured

# Further (partly current) research

- Automatic creation of additional covariates based on the polynomes and interactions of the original ones as well as sigmoid functions of them (automatic feature extraction), based on an outer genetic algorithm (already implemented)

*$l(\text{erf}(l(-(X37)*((X54))))))$  added after  $2^8$  steps*

*$l((l(-(X23)*((X57))))))$  added after  $2^{12}$  steps*

*...*

*$l(\tanh(l((X73))))$  replaced  $l((l((X81)*((X68))))))$  after  $2^{16}$  steps*

*$l((l((X71)*((X69))))))$  replaced  $l(\text{erf}(l(((X54))))))$  after  $2^{18}$  steps*

*...*

- Allowing the search over different choices of the random effect structures (to be addressed)
- Allowing the search over different choices of the response distributions (to be addressed)

# Concluding remarks

- We introduced the MJMCMC approach for estimating posterior model probabilities and Bayesian model averaging and selection.
- It incorporates the ideas of MCMC with possibility of large jumps combined with local optimizers to generate proposals in the discrete space of models
- *EMJMCMC* R-package is developed and available from the GitHub repository: <http://aliaksah.github.io/EMJMCMC2016/>
- The developed package gives a user high flexibility in the choice of methods to obtain marginal likelihoods and model selection criteria within GLMM
- Extensive parallel computing for both MCMC moves and local optimizers is available within the developed package
- Based on the obtained in the experimental part results, we can claim MJMCMC to be a rather competitive novel algorithm that both performs well in terms of the search quality and addressed a more general class of statistical models than the competing approaches
